

A large, billowing white cumulus cloud dominates the center of the frame, rising from a layer of lower clouds. The sky is a clear, vibrant blue. The text "Warming the Earth and the Atmosphere-I" is overlaid in red, bold, sans-serif font across the middle of the cloud.

# Warming the Earth and the Atmosphere-I

*GEOL 1350: Introduction To Meteorology*

# Overview

- **Some basic thermodynamic concepts**
- **Temperature**
- **Heat transfer in the atmosphere**

**Energy - the capacity to do work**

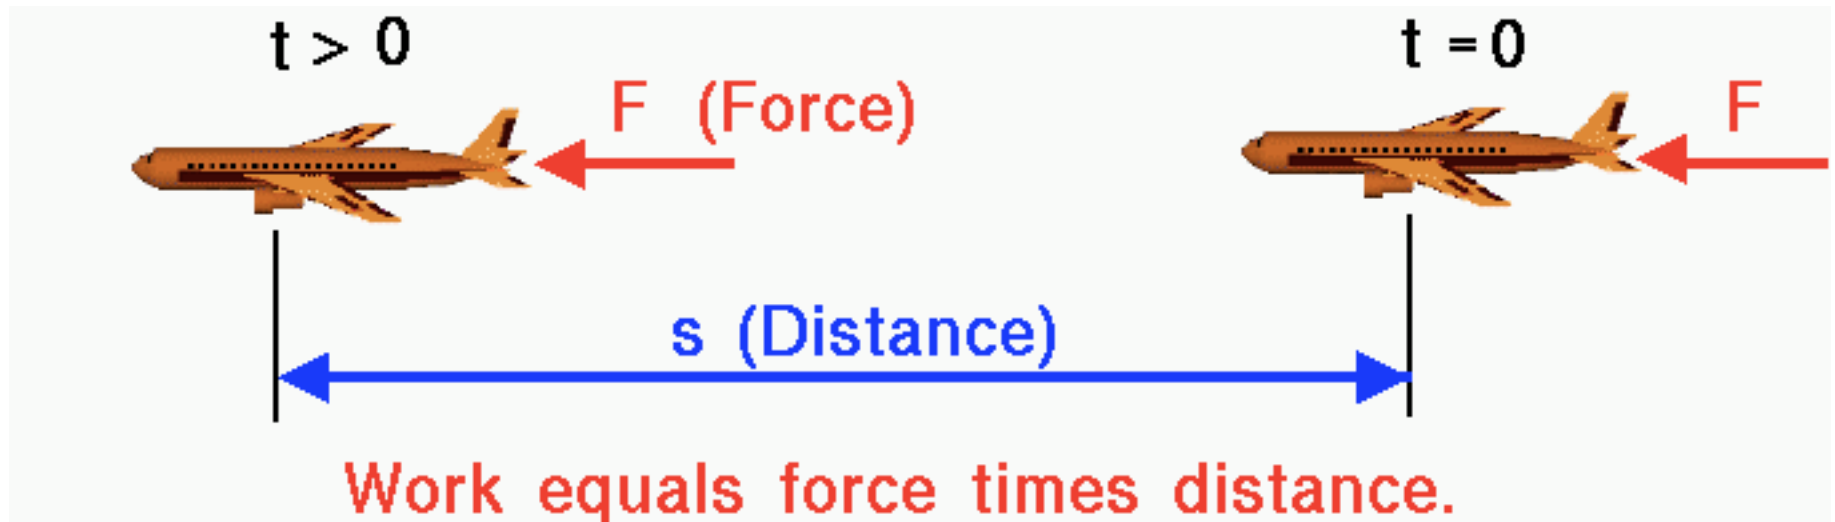

***Work*** is done on an object when a force moves it.

How do we decided how much work is done?

The amount of work done is the ***distance*** traveled times the ***force*** in the direction of displacement

$$\text{Work} = \text{Force} \cdot \text{Distance}$$

# Energy - the capacity to do work

$$\text{Work} = \text{Force} \cdot \text{Distance}$$

# Forms of energy

***kinetic energy*** is the work that a body can do by virtue of its motion  $KE = \frac{1}{2} m v^2$

***Potential energy*** is the work an object can do as a result of relative position, or the *potential* to do work, or stored energy that can be converted to other forms of energy.

$PE = m \times g \times h$   $m$  - mass,  $g$  - acceleration of gravity,  $h$  – object's height above ground

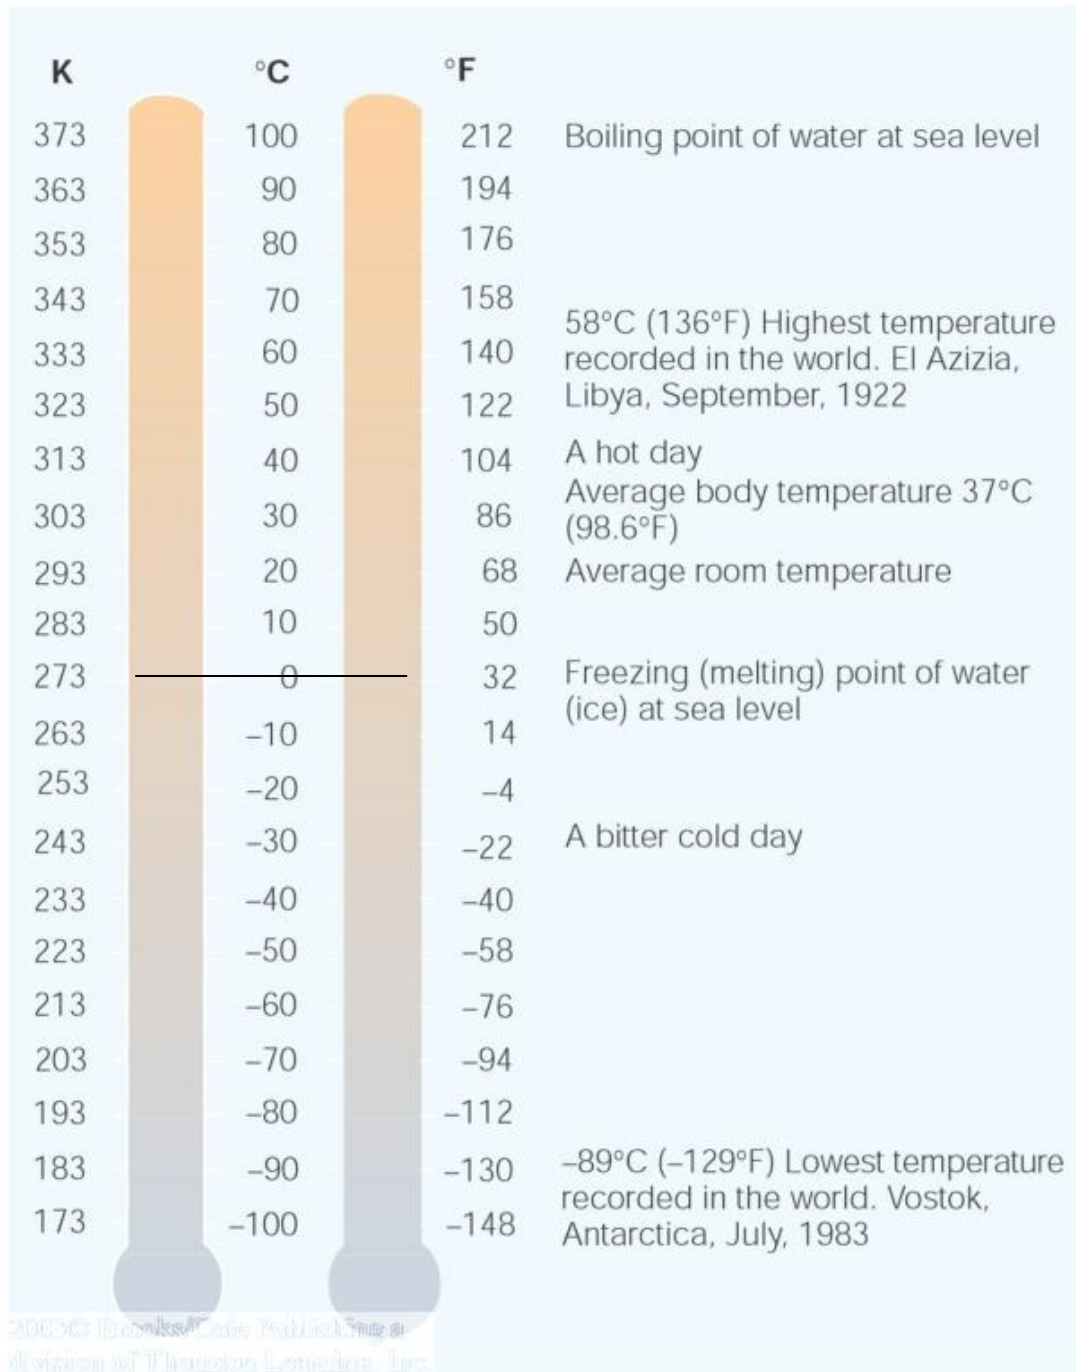

***Internal Energy*** – total energy stored in an object (potential + kinetic)

***Temperature*** is a measure of average kinetic energy of a substance; simply, is a measure of average speed of air molecules

***High*** temperatures corresponds to ***faster*** average molecule speeds

**Temperature scales** - three commonly used scales:

- Fahrenheit (°F)
- Celsius (°C)
- Kelvin (K)

**Fahrenheit (°F) and Celsius (°C) scales are calibrated to freezing and boiling water, but the Celsius range is 1.8 times more compact**

**The Celsius and Kelvin scales are the same except that K is 273.16 degree higher than °C**

$$K = °C + 273.16$$

## Conversation between °F and °C

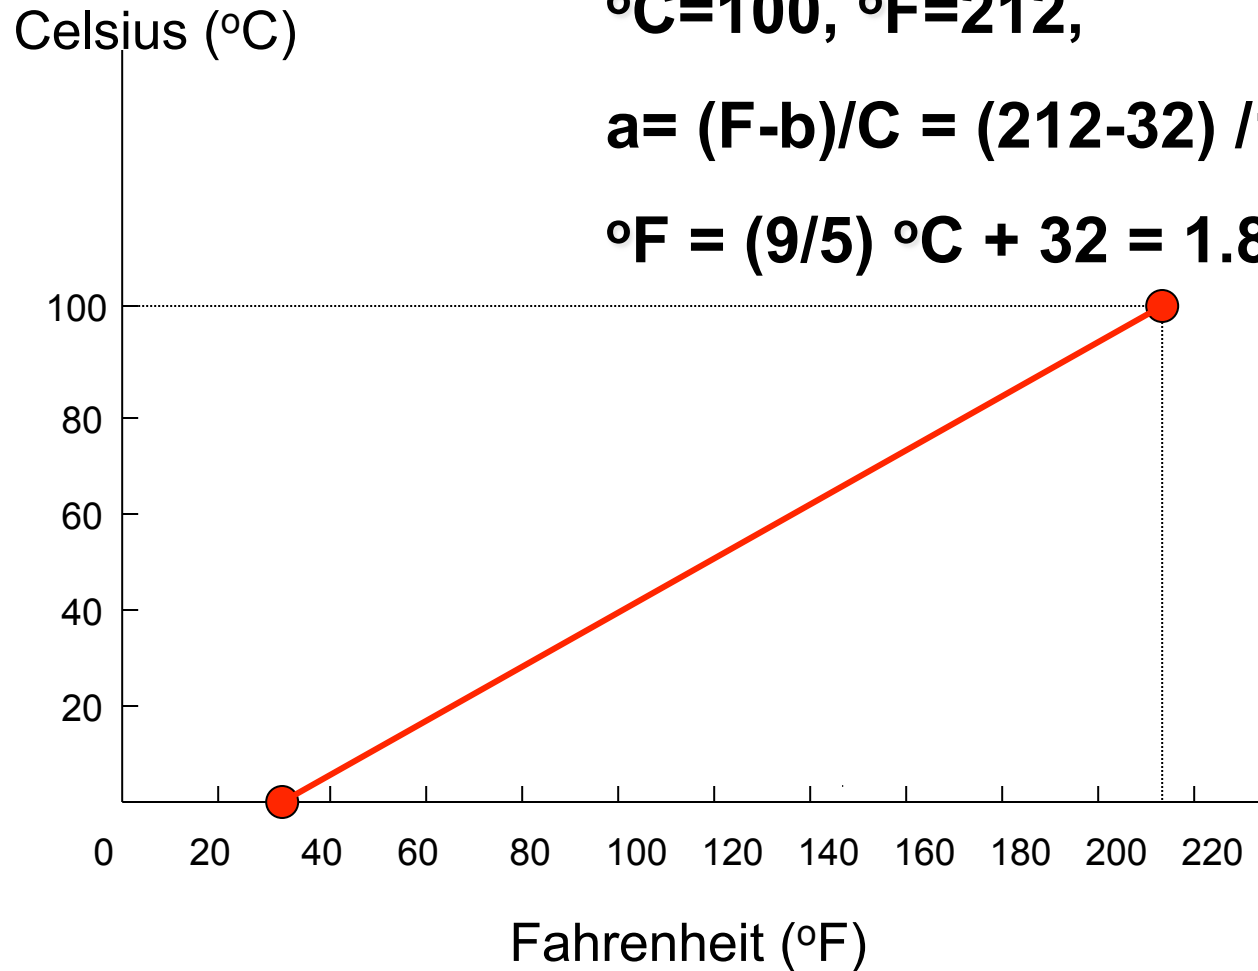

$$F = a \cdot C + b$$

$$^{\circ}\text{C}=0, ^{\circ}\text{F}=32, \rightarrow b=32$$

$$^{\circ}\text{C}=100, ^{\circ}\text{F}=212,$$

$$a = (F-b)/C = (212-32) / 100 = 9/5 = 1.8$$

$$^{\circ}\text{F} = (9/5) ^{\circ}\text{C} + 32 = 1.8 ^{\circ}\text{C} + 32$$

**1) Convert temperature from 10°C to Kevin (K) and Fahrenheit (°F)**

$$10 + 273.16 = 283.16 \text{ K}$$

$$1.8 \times 10 + 32 = 50 \text{ F}$$

**2) Convert temperature from 20°C to Kevin (K) and Fahrenheit (°F)**

$$20 + 273.16 = 293.16 \text{ K}$$

$$1.8 \times 20 + 32 = 68 \text{ F}$$

## ***What is Heat ?***

The energy *transferred* between objects as a result of the *temperature difference* between them

## **Unit for heat**

***calorie (cal)*** is the energy needed to raise temperature of 1 gram of water 1 degree Celsius

**1 cal = 4.186 Joule    or**

**1 Joule = 0.2389 cal**

**The temperature change of an object depends on -**

**How much heat is being added**

**The amount of matter**

**The **heat capacity** of the substance**

**Heat capacity** of a substance is the ratio of the amount of heat energy absorbed by the substance to its corresponding temperature rise

$$C_p = \text{heat input} / \text{temperature rise}$$

**Specific heat** of a substance is heat capacity of the substance per unit mass

$$c_p = C_p / m$$

or, is the amount of heat required to increase the temperature of 1 gram of that substance 1 degree Celsius (cal/g/°C, or j/kg/°C)

# Specific Heat of common substances

Specific heat		
Substance	cal / g / °C	J/kg/ °C
Water	1.0	4186
Ice	0.50	2093
Air	0.24	1005
Sand	0.19	798

**Sensible heat can be sensed by human. It's heat associated with temperature change.**

$$\Delta Q = m C_p \Delta T$$

***How much sensible heat is needed to warm 1 kg of dry air by 10°C?***

$$\Delta Q = 1 \text{ kg} \cdot 1005 \text{ J/kg/}^\circ\text{C} \cdot 10^\circ\text{C} = 10050 \text{ J}$$

## ***Latent heat:***

Heat required to change a substance from one state to another. It is a *hidden* heat until phase changes occur.

***Latent Heat is an Important source of atmospheric energy***

$$\Delta Q_L / m_{\text{air}} = L$$

$$L_v = \pm 2.5 \times 10^6 \text{ J kg}^{-1} \quad \text{condensation/evaporation}$$

$$L_f = \pm 0.334 \times 10^6 \text{ J kg}^{-1} \quad \text{fusion or melting}$$

$$L_d = \pm 2.83 \times 10^6 \text{ J kg}^{-1} \quad \text{deposition or sublimation}$$

# Heat exchange with environment during phase change

As water moves toward vapor it absorbs latent heat to keep the molecules in rapid motion<sup>16</sup>

# Phase Changes

# Heat Transfer in the Atmosphere

- **Conduction**
- **Convection**
- **Advection**
- **Radiation**

# Conduction

**Conduction** of heat energy **occurs** as **warmer molecules transmit** vibration, and hence **heat**, to adjacent **cooler molecules**.

**Warm ground surfaces heat** overlying **air** by **conduction**.

# Heat transfer in the atmosphere

## Conduction –

- the process of heat transfer from **molecule to molecule**
- molecules transfer energy by coming into **contact** with one another
- conduction requires **contact**
- heat transferred by conduction ***always*** flows from warmer to colder regions

**The amount of heat transferred by conduction depends on-**

- 1. Temperature difference between the two objects**
- 2. Their *thermal (heat) conductivity* – the ability of a substance to conduct heat by molecular motions**

## ***Heat conductivity of common substances***

<b>Substance</b>	<b>Heat conductivity (W/m/°C)</b>
<b>still air</b>	<b>0.023</b>
<b>wood</b>	<b>0.08</b>
<b>dry soil</b>	<b>0.25</b>
<b>water</b>	<b>0.60</b>
<b>snow</b>	<b>0.63</b>
<b>ice</b>	<b>2.1</b>
<b>iron</b>	<b>80</b>

***Air is a extremely poor conductor ! Inefficient for heat transfer in the atmosphere***

# Heat Transfer in the Atmosphere - Convection

where air moves from one place to another, carrying its heat energy with it

***Convection always requires motion !***

in atmospheric science, *convection* is usually associated with vertical movement of the fluid (air or water) - hot air rises

# Convection

**The rate of energy transferred by convection depends on the temperature of the rising air parcel compared to the temperature of its surrounding atmosphere**

- **strong in summer and weak in winter**
- **strong over tropics and weak in polar region**

**A efficient way to transfer heat in the atmosphere!**

- Air parcel that rises will expand and cool
- Air that sinks is compressed and warmed

Why ?

Because atmospheric pressure always decrease with height

# Advection

**Horizontally moving part of the circulation (called wind) carries properties of the air in that particular area with it.**

**The transfer of these properties by horizontally moving air is called **advection**.**

# Summary

1. The **temperature** of a substance is a measure of the **average speed** of its atoms and molecules. **Faster** the air molecules **move**, the **higher** the **temperature**.
2. **Evaporation** (transformation of liquid to vapor) is a **cooling** process and **condensation** (transformation of vapor into liquid) is a **warming** process.
3. Heat is energy transferred from one object to another because of **temperature difference** between them.
4. The transfer of heat within our atmosphere can take place by **conduction, convection and radiation**.
5. Air is a poor conductor of heat.
6. **Convection** is an **important mechanism** of heat transfer, as it represents the vertical movement of **warmer air upward** and **cooler air downward**.
